

Interpreting the Slope and the y -Intercept

- What is the meaning of the slope?
- What is the meaning of the y -intercept?

What must one consider when collecting data?

- What is being measured?
- Is there one variable or more than one variable?
 - What is (are) the unit(s) for the variable(s)?
- For what or how will the data be used?
- What does the data mean?

What are some considerations for data collection?

- Understand what is being measured?
- Determine how many variables must be defined?
 - Determine the unit(s) for the variable(s).
- Determine how the data is to be collected. Choose the measurement device(s) carefully.
- Determine the amount of data to be collected.

How could we determine the thickness of the hard cover of a textbook and the thickness of a page in a textbook using an ordinary ruler?

- Measurement device: a transparent six-inch ruler with fine measurements to $\frac{1}{32}$ inch as well as millimeters
- Measure the thickness of the front cover with various amounts of pages from the text: create linear function and use function to determine desired information

How could we determine the thickness of the hard cover of a textbook and the thickness of a page in a textbook using an ordinary ruler?

- Problems -
 - How one holds the ruler
 - ◉ Edge from which one measures the thickness
 - ▣ Best to make consistent measurements

How could we determine the thickness of the hard cover of a textbook and the thickness of a page in a textbook using an ordinary ruler?

- Problems -
 - How tightly one holds/pinches the pages with the front cover
 - ◉ Human error?
 - Most hard cover books have an end page
 - ◉ Tear out or keep in?

How could we determine the thickness of the hard cover of a textbook and the thickness of a page in a textbook using an ordinary ruler?

- Question - Why "sheets of paper" rather than "pages"?
- Answer - A sheet of paper in a book has two pages, one on each side. A sheet of paper has thickness that can be determined.

How could we determine the thickness of the hard cover of a textbook and the thickness of a page in a textbook using an ordinary ruler?

- Considerations - One must be careful to count the pieces of paper rather than relying on page numbers.
 - Some pages in a book may be numbered with Roman numerals or with special page numbering systems.

The data on the next slide is presented for your consideration. The data was carefully collected and all measurements were made with a transparent ruler with the described attributes.

- Note: Measurements of the thickness were made in inches as well as in centimeters.

What does this data mean?

- The first column is the number of sheets of paper used in each measurement.
- The thicknesses measured, in inches in the second column and in centimeters in the third column, are the thickness of the front cover, one end page, and the number of sheets of paper specified in the first column.

What is x and what is y ?

- Since the thickness measured depends on the number of sheets of paper involved in the measurement, the number of sheets of paper is the independent variable, x , and the thickness of the front cover, the end page, and the specified number of sheets of paper is the dependent variable, y .

Define y in terms of x - general

- Y is the thickness of the front cover, one end page and x sheets of paper of the textbook *Statistics in Action - Understanding a World of Data*.

Define y in terms of x - for

What are the units on the slope?

Since the slope is the ratio of the vertical change, the rise, to the horizontal change, the run,

$$\frac{\text{rise}}{\text{run}} = \frac{\text{change in } y}{\text{change in } x}$$

the units on the slope are

$$\frac{\text{units on the rise}}{\text{units on the run}} = \frac{y\text{-units}}{x\text{-units}}$$

A one-unit change in x

Let's interpret the slope

- Thickness measured in inches
 - Units: inches per sheet
 - $m = 0.0025$ expressed as a fraction with a denominator of 1: $0.0025/1$ where
 - ◉ 1 is the change in the number of sheets of paper
 - ◉ A positive change is an increase
 - ◉ *One additional page*

**Let's interpret the y -intercept
for the least squares line.**

Let's interpret the y -intercept for the least squares line.

- Why the y -intercept of the least squares line instead of the y -coordinate of the y -intercept of the least squares line?

Let's interpret the y -intercept for the least squares line.

- Why the y -intercept of the least squares line instead of the y -coordinate of the y -intercept of the least squares line?
 - The y -value depends on the x -value.
 - We cannot interpret a y -value without its corresponding x -value.

Let's interpret the y -intercept for the least squares line.

- So, what is the corresponding x -value?

Let's interpret the y -intercept for the least squares line.

- So, what is the corresponding x -value?
 - Two ways to remember this:
 - ◉ Since on the y -axis, x is equal to zero, the coordinates of the y -intercept are $(0, b)$.
 - ◉ Given the equation, $y = mx + b$, what x do we need so that y will be equal to b ? We need $x = 0$. So, again, the coordinates of the y -intercept are $(0, b)$.
 - That is, when $x = 0$ then $y = b$.

Let's interpret the y -intercept for the least squares line.

- Does it matter if we say “when $x = 0$ then $y = b$ ”?

Let's interpret the y -intercept for the least squares line.

- Does it matter if we say “when $x = 0$ then $y = b$ ”? **YES!**
 - The value of y depends on x .
 - x is the independent variable, the free variable, the explanatory variable. The x -value is free to change.
 - y is the dependent variable, the response variable. The y -value depends on the x -value. The y -value responds to changes in the x -value.

Let's interpret the y-intercept for the least squares line.
